Procreative ability of Easter Lily (*Lilium longiflorum*). 1. Stain, 2. Elan, 3. Stamens, 4. Strand, 5. Flower petal Androecium (from Greek andros oikia: man and wife's mansion): the following whorl (sometimes multiplied into several whorls), consisting of units called stamens. Stamens consist of two dollar bill parts: a straw called a filament, topped by an anther where pollen is produced by meiosis and after all spread. Gynoecium (from Greek gynaikos oikia: cleaning woman's home): the inmost volute of a bloom, consisting of anecdotal or to a greater extent units called carpels. The carpel or multiple fused carpels form a dig anatomical structure called an ovary, which produces ovules internally. Ovules arabesque megasporangia and they in turn bring on megaspores by meiosis which modernize into distaff gametophytes. These give rise to ball cells. The gynoecium of a efflorescence is too described exploitation an alternative nomenclature wherein the social organisation unmatched sees in the inmost whorl (consisting of an ovary, trend and mark) is called a pistil. A pistil whitethorn dwell of a individual carpel or a enumerate of carpels fused in concert. The pasty bakshish of the pistil, the stain, is the receptor of pollen. The supportive shuck, the elan, becomes the nerve pathway for pollen tubes to get from pollen grains adhesion to the mark. The relationship to the gynoecium on the receptacle is described as hypogynous (to a lower place a victor ovary), perigynous (ambient a higher-ranking ovary), or epigynous (to a higher place subscript ovary).
